Aerofoil

The present invention relates to aerofoils and more particularly to appropriate cooling of such aerofoils when 5 cooling channels become blocked.

Aerofoils are used within turbine engines and are subjected to high temperatures such that adequate cooling is, required to maintain their operability. Typically, cooling channels are provided through the aerofoil in which coolant, normally air, flows in order to cool the airflow. Unfortunately, these internal cooling channels are prone to blockage by dirt or other contaminants.

Previous approaches to avoiding coolant channel blockage have included channel oversizing, over specifying the number of cooling channels required and incorporation of dirt separation or filtration devices. These approaches inherently result in significant efficiency penalties along with additional fabrication and manufacturing costs.

In accordance with the present invention there is provided an aerofoil for a turbine engine, the aerofoil comprising cooling channels of decreasing cross-section with a transfer passage between adjacent cooling channels in order to provide coolant flow into a channel if normal coolant flow is restricted upstream of the transfer passage.

Preferably, cooling channels are wedge shaped from an inlet to an outlet to provide the decreasing cross-section to coolant flow. Generally, transfer passages will be provided in both sides of each cooling channel. Normally, the or each transfer passage cross-section accumulation is determined for substantial conformity with their coolant channel outlet cross-section for coolant flow balance through the aerofoil. Possibly, more than one transfer passage will be provided between adjacent cooling channels. Typically, transfer passages will have a one millimetre

Possibly, transfer passages are staggered to

diameter.

improve heat transfer and/or mechanical strength in the aerofoil. Normally, transfer passages are located towards an upstream end of each cooling channel. Possibly, the relative cross-section and distribution of transfer passages between adjacent cooling channels and/or through the length of the aerofoil may be different in order to facilitate desired cooling of the aerofoil.

Also in accordance with the present invention there is provided a turbine engine including an aerofoil as described above.

10

An embodiment of the present invention will now be described by way of example only with reference to the accompanying drawing, Figure 1, which is a schematic representation of cooling channels in an aerofoil.

15 Referring to the drawing Fig. 1 which provides a schematic representation of an aerofoil 1 including cooling channels 2,3,4,5. Generally, the cooling channels 2,3,4,5, have a wedge configuration such that an inlet end 6 has a significantly greater cross-section than an outlet end 7. Thus, each of the cooling channels 2,3,4,5 has a decreasing 20 cross-section presented to an airflow in the direction of the arrowheads. The rate of coolant airflow (arrowheads A) through the channels 2,3,4,5 will be dependent upon turbine engine speed and cooling requirements. Ιt will 25 appreciated that heating of the aerofoil 1 will be dependant upon turbine engine operation or condition and so of cooling required may be the degree Nevertheless, the aerofoil 1 will typically require ongoing cooling whilst operational and any failure will compromise aerofoil performance. 30

In the present aerofoil 1 transfer passages 8 are provided between adjacent cooling channels 2,3,4,5. In normal use, as a result of the equalisation of airflow pressure in the adjacent channels 2,3,4,5 there will be negligible, if any, transfer airflow through the passages 8 and therefore between the channels 2,3,4,5. However, when

a channel such as cooling channel 4 is blocked by a blockage 9 there is a diminution in the flow pressure in that channel 4 if only partly blocked or an absence of coolant airflow pressure if completely blocked. 5 circumstances, the coolant airflow pressure in adjacent coolant channels 3,5 will force air through the passages 8 in the direction of arrowheads B in order to provide cooling in that channel 4. The effective constriction in channels 3,4,5 due to decreasing cross-section the 10 effectively pressurises the coolant airflows in these channels 3,4,5 and the desire to equalise pressure through the passage 8 substantially drives air into the channel 4 and renders any venturi effect due to the airflow past the passage 8 in the respective channels 3,5 irrelevant.

It will be noted that airflow in channel 2 may not be 15 the respective passage 8 between that through its adjacent channel channel 2 3 if there and is substantially the same airflow pressure in these channels However, if the leakage of air though the respective passage 8 between channels 3 and blocked channel 4 20 sufficient to diminish the flow pressure in channel 3 then the balance in airflow pressure between channel 2 and channel 3 will be disturbed and there may be some airflow through the respective passage 8 between the channels 2,3 25 to compensate. There may be a cascade of transfer airflow in the passages 8 progressively decreasing away from the blocked channel.

As can be seen in Fig. 1 transfer passages 8 are provided on either side of central coolant channels 2,3 whilst outer coolant channels 2,5 only have one transfer passage 8 with their adjacent coolant channel 2,3. In such circumstances, central coolant channels 2,3 can receive coolant airflow through respective passages 8 from either adjacent channel when blocked whilst outer channels 2,5 will only receive coolant flow through one passage 8 when blocked. This situation may be acceptable if the outer

35

portions of the aerofoil 1 are subjected to less heating and therefore less coolant is required in the outer channels 2,5. Alternatively, these outer coolant channels 2,5 could incorporate more than one transfer passage with adjacent coolant passages in order that potentially greater coolant flow may pass through these additional transfer passages to improve cooling. Nevertheless, it will be that by having a wedge cross-section appreciated configuration each channel 2,3,4,5 is diminishing from its 10 inlet end 6 to its outlet end 7 so that it may be difficult to accommodate several transfer passages in the length of channels 2,3,4,5. Furthermore, it appreciated that incorporation of transfer passages should not appreciably diminish the mechanical strength of the aerofoil 1. 15

As illustrated in Fig. 1, typically the transfer passages 8 will comprise round holes between adjacent channels 2,3,4,5. Normally, these holes will have a diameter of approximately 1 millimetre. Alternatively, the transfer passages may have different cross-sections including oval, lozenge or square.

20

30

Retention of mechanical strength in the aerofoil is Thus, in order to break any important. potential the transfer passages in structural lines of weakness, adjacent channels may be staggered out of alignment with each other. Furthermore, rather than being axially aligned within the aerofoil 1 each passage could be slanted relative to the major axis of the aerofoil to facilitate guidance or scoop pickup when required between adjacent coolant channels due to a blockage of one or more such coolant channels. Furthermore, these passages could have a herringbone or arrowhead arrangement of intersecting slope sections to the major axis of the aerofoil 1.

As indicated previously, accommodation of the transfer 35 passages 8 may be difficult due to the thin nature of the aerofoil 1 and compounded by the wedge cross-section

configuration. Thus, normally the transfer passages 8 will be located towards an upstream end of the coolant channels 2,3,4,5, that is to say towards the inlet ends 6.

The cross-section provided by respective transfer 5 passages 8 will typically be determined for substantial conformity with the outlet end 7 cross-section of each coolant channel 2,3,4,5. Such an arrangement should ensure coolant flow balance between the respective coolant channels 2,3,4,5. In such circumstances, the aerofoil 1 will be substantially cooled throughout its length with substantially the same or a desired cooling effect through each of the channels 2,3,4,5 irrespective of blockage 9.

As indicated previously, transfer passages 8 during normal open operation for all channels will be redundant in terms of limited, if any, transfer airflow between the 15 In such circumstances, the relatively high channels. pressure and airflow rates through the channels along with the perpendicular presentation of that airflow should limit the possibility of dirt blocking these transfer passages 8. In any event, if the transfer passage 8 was substantially 20 blocked during normal operation this blockage would not be compacted and so should be relatively Furthermore, if any inlet end were blocked then there would be no back up pressure behind such a loose blockage in a transfer passage and the adjacent airflow pressure may 25 drive the blockage out or through the transfer passage and out of the blocked channel.

The present aerofoil 1 will generally be used in a turbine engine. The operation of turbine engines is well known by those skilled in the art. It will be appreciated that aerofoil fins are subjected to substantial heating during their operation but are required to retain substantially consistentstructural configuration In such circumstances, an aerofoil must remain strength. within specified temperature ranges in order to retain structural conformity and strength for consistent turbine

30

35

operation. Blockage of cooling channels described previously will alter cooling within the aerofoil both collectively and locally about the blocked cooling In such circumstances, the aerofoil may rapidly 5 deteriorate in operation and require potentially expensive replacement. The present invention also includes a turbine engine including an aerofoil as described previously such greater confidence can be provided that individual aerofoil will be adequately cooled such that planned and preventative replacement of aerofoils for operational confidence can be extended over longer periods of time or service history.

Whilst endeavouring in the foregoing specification to draw attention to those features of the invention believed to be of particular importance it should be understood that the Applicant claims protection in respect of any patentable feature or combination of features hereinbefore referred to and/or shown in the drawings whether or not particular emphasis has been placed thereon.
